LAB REPORT

on

Artificial Intelligence (23CS5PCAIN)

Submitted by

Sarvesh Rastogi (1BM22CS247)

in partial fulfillment for the award of the degree of

BACHELOR OF ENGINEERING

in

COMPUTER SCIENCE AND ENGINEERING

B.M.S. COLLEGE OF ENGINEERING

(Autonomous Institution under VTU)

BENGALURU-560019

Sep-2024 to Jan-2025

**B.M.S. College of Engineering,
Bull Temple Road, Bangalore 560019**
(Affiliated To Visvesvaraya Technological University, Belgaum)
Department of Computer Science and Engineering

CERTIFICATE

This is to certify that the Lab work entitled “Artificial Intelligence (23CS5PCAIN)” carried out by **Sarvesh Rastogi (1BM22CS247)**, who is Bona fide student of **B.M.S. College of Engineering**. It is in partial fulfilment for the award of **Bachelor of Engineering in Computer Science and Engineering** of the Visvesvaraya Technological University, Belgaum. The Lab report has been approved as it satisfies the academic requirements in respect of an Artificial Intelligence (23CS5PCAIN) work prescribed for the said degree.

Program 1

Implement Tic - Tac - Toe Game

Algorithm:

Code:

```
# Set up the game board as a 2D list
```

```
board = [["-", "-", "-"],  
         ["-", "-", "-"],  
         ["-", "-", "-"]]
```

```

# Define a function to print the game board
def print_board():
    for row in board:
        print(" | ".join(row))

# Define a function to handle a player's turn
def take_turn(player):
    print(player + "'s turn.")
    position = input("Choose a position from 1-9: ")
    while position not in ["1", "2", "3", "4", "5", "6", "7", "8", "9"]:
        position = input("Invalid input. Choose a position from 1-9: ")
    position = int(position) - 1
    row, col = divmod(position, 3)
    while board[row][col] != "-":
        position = int(input("Position already taken. Choose a different position: ")) - 1
        row, col = divmod(position, 3)
    board[row][col] = player
    print_board()

# Define a function to check if the game is over
def check_game_over():
    # Check for a win
    for i in range(3):
        if board[i][0] == board[i][1] == board[i][2] != "-":
            return "win"
        if board[0][i] == board[1][i] == board[2][i] != "-":
            return "win"
    if board[0][0] == board[1][1] == board[2][2] != "-":
        return "win"
    if board[0][2] == board[1][1] == board[2][0] != "-":
        return "win"
    # Check for a tie
    elif all(cell != "-" for row in board for cell in row):
        return "tie"
    # Game is not over
    else:
        return "play"

# Define the main game loop
def play_game():
    print_board()
    current_player = "X"
    game_over = False
    while not game_over:
        take_turn(current_player)
        game_result = check_game_over()
        if game_result == "win":
            print(current_player + " wins!")

```

```

    game_over = True
    elif game_result == "tie":
        print("It's a tie!")
        game_over = True
    else:
        # Switch to the other player
        current_player = "O" if current_player == "X" else "X"

# Start the game
play_game()

```

Output:

- | - | -
- | - | -
- | - | -

X's turn.

Choose a position from 1-9: 1

X | - | -
- | - | -
- | - | -

O's turn.

Choose a position from 1-9: 2

X | O | -
- | - | -
- | - | -

X's turn.

Choose a position from 1-9: 3

X | O | X
- | - | -
- | - | -

O's turn.

Choose a position from 1-9: 5

X | O | X
- | O | -
- | - | -

X's turn.

Choose a position from 1-9: 4

X | O | X
X | O | -
- | - | -

O's turn.

Choose a position from 1-9: 6

X | O | X
X | O | O
- | - | -

X's turn.

Choose a position from 1-9: 8

X | O | X

X | O | O

- | X | -

O's turn.

Choose a position from 1-9: 7

X | O | X

X | O | O

O | X | -

X's turn.

Choose a position from 1-9: 9

X | O | X

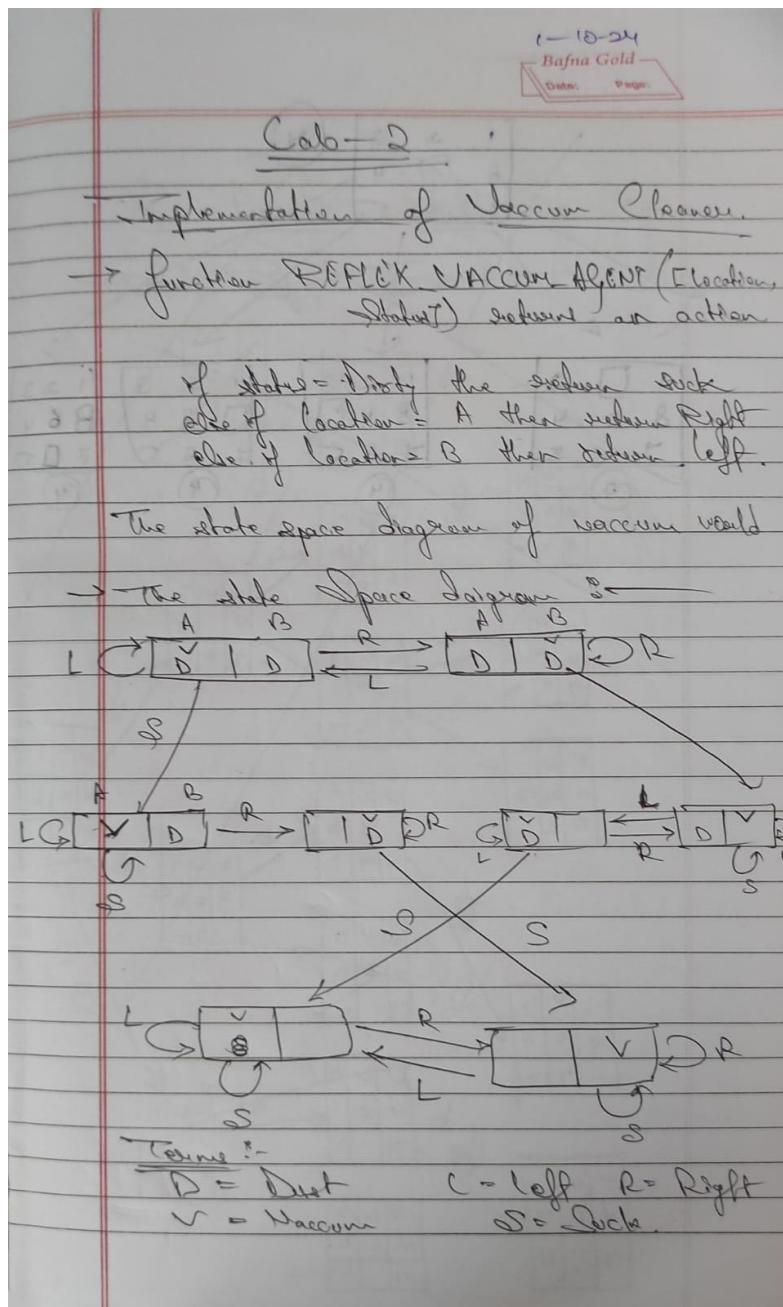

X | O | O

O | X | X

It's a tie!

Implement vacuum cleaner agent

Algorithm:

Code:

```

Moving to Room C...

Cleaning Room C...

Current status:

Room A: Clean

Room B: Clean

Room C: Clean

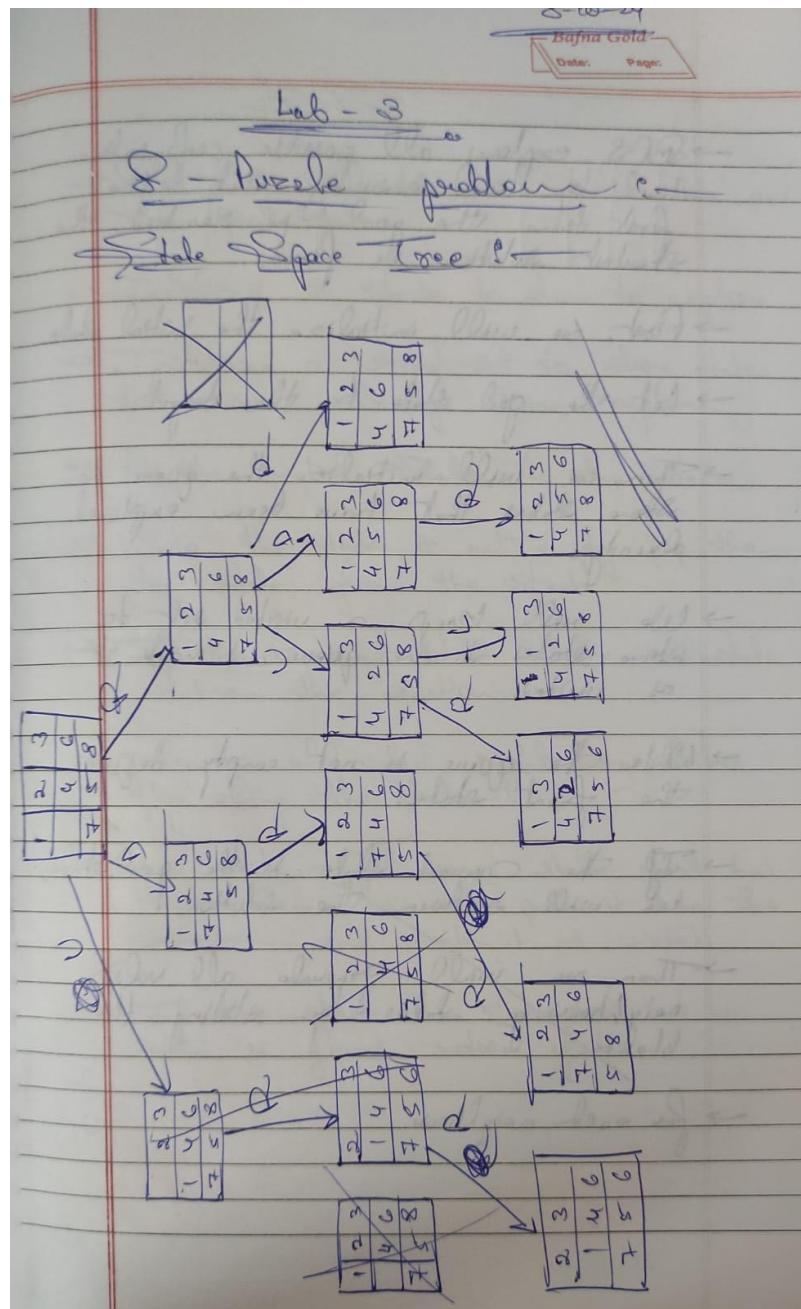

Room D: Clean

All rooms are now clean! Total cost: 1

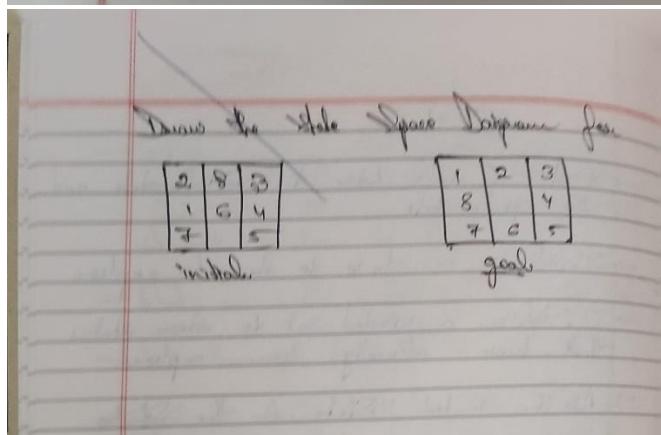

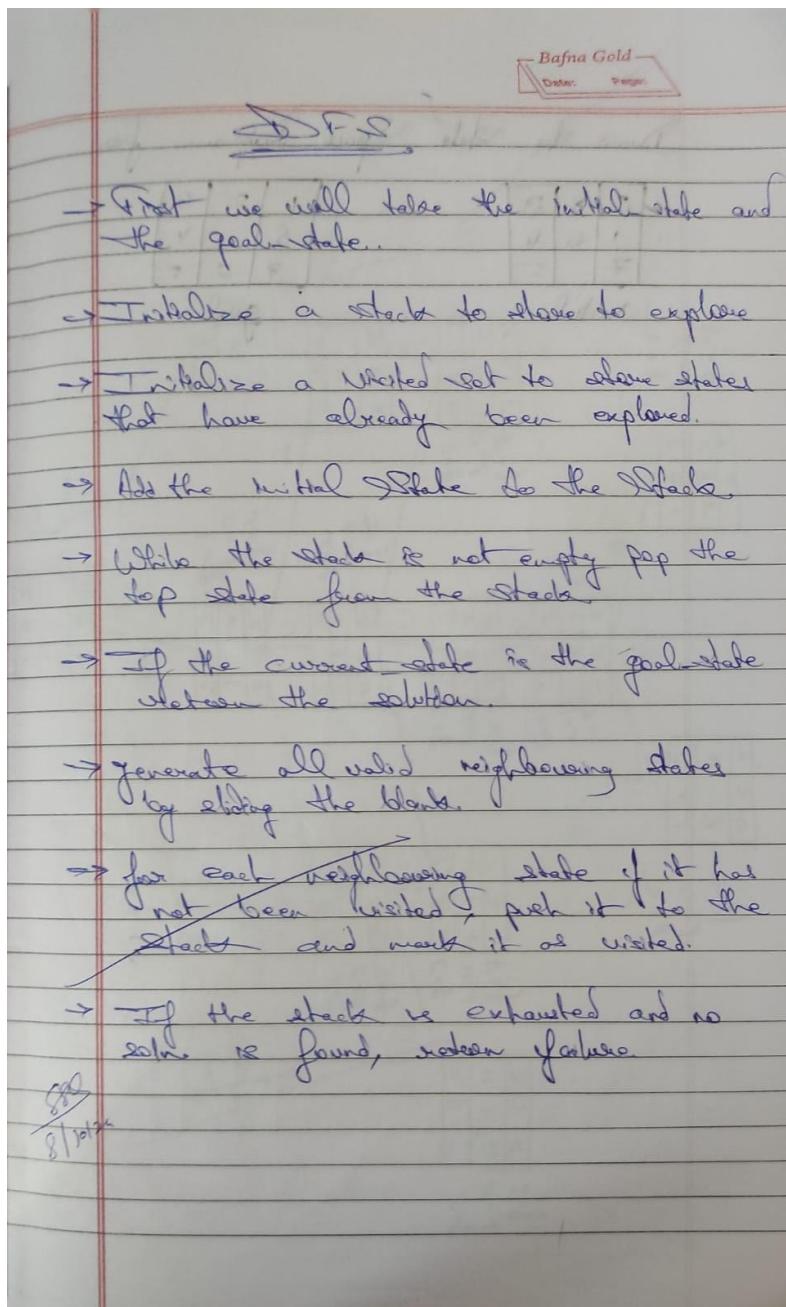

Program 2

Implement 8 puzzle problems using Depth First Search (DFS)

Algorithm:

- BFS explores all possible configurations level by level ensuring that the first time the goal is reached, the shortest solution is found.
- First, we will initialize the initial state.
- Let the goal state be the target.
- Then, we will initialize the queue to store states that have been explored already.
- We will keep a visited set to store states in the queue and mark it as visited.
- While the queue is not empty, dequeue the front state.
- If the current state is the goal state, we will return the solution.
- Then we will generate all valid neighbouring states by sliding the blocks.
 - for each neighbour,

Code:

```
from collections import deque

def dfs(start, max_depth):
    stack = deque([(start, [start], 0)]) # (node, path, level)
    visited = set([start])
    all_moves = []
    while stack:
        node, path, level = stack.pop()
        all_moves.append((path, level))
        if level < max_depth:
            for next_node in get_neighbors(node):
                if next_node not in visited:
                    visited.add(next_node)
                    stack.append((next_node, path + [next_node], level + 1))
    return all_moves

def get_neighbors(node):
    neighbors = []
    for i in range(9):
        if node[i] == 0:
            x, y = i // 3, i % 3
            for dx, dy in [(-1, 0), (1, 0), (0, -1), (0, 1)]:
                nx, ny = x + dx, y + dy
                if 0 <= nx < 3 and 0 <= ny < 3:
                    n = list(node)
                    n[i], n[nx * 3 + ny] = n[nx * 3 + ny], n[i]
                    neighbors.append(tuple(n))
        break
    return neighbors

def print_board(board):
    board = [board[i:i+3] for i in range(0, 9, 3)]
    for row in board:
        print(" | ".join(str(x) for x in row))
        print("-----")

def main():
    start = tuple(int(x) for x in input("Enter the initial state (space-separated): ").split())
    max_depth = 10 # maximum depth to search
    all_moves = dfs(start, max_depth)
    if all_moves:
        print("All possible moves:")
        for i, (path, level) in enumerate(all_moves):
            print(f"Move {i+1}:")
            for j, node in enumerate(path):
                print(f"Step {j}:")
                print_board(node)
```

```

        print()
        print(f"Number of moves: {level}")
        print()
else:
    print("No solution found.")

if __name__ == "__main__":
    main()

```

Output:

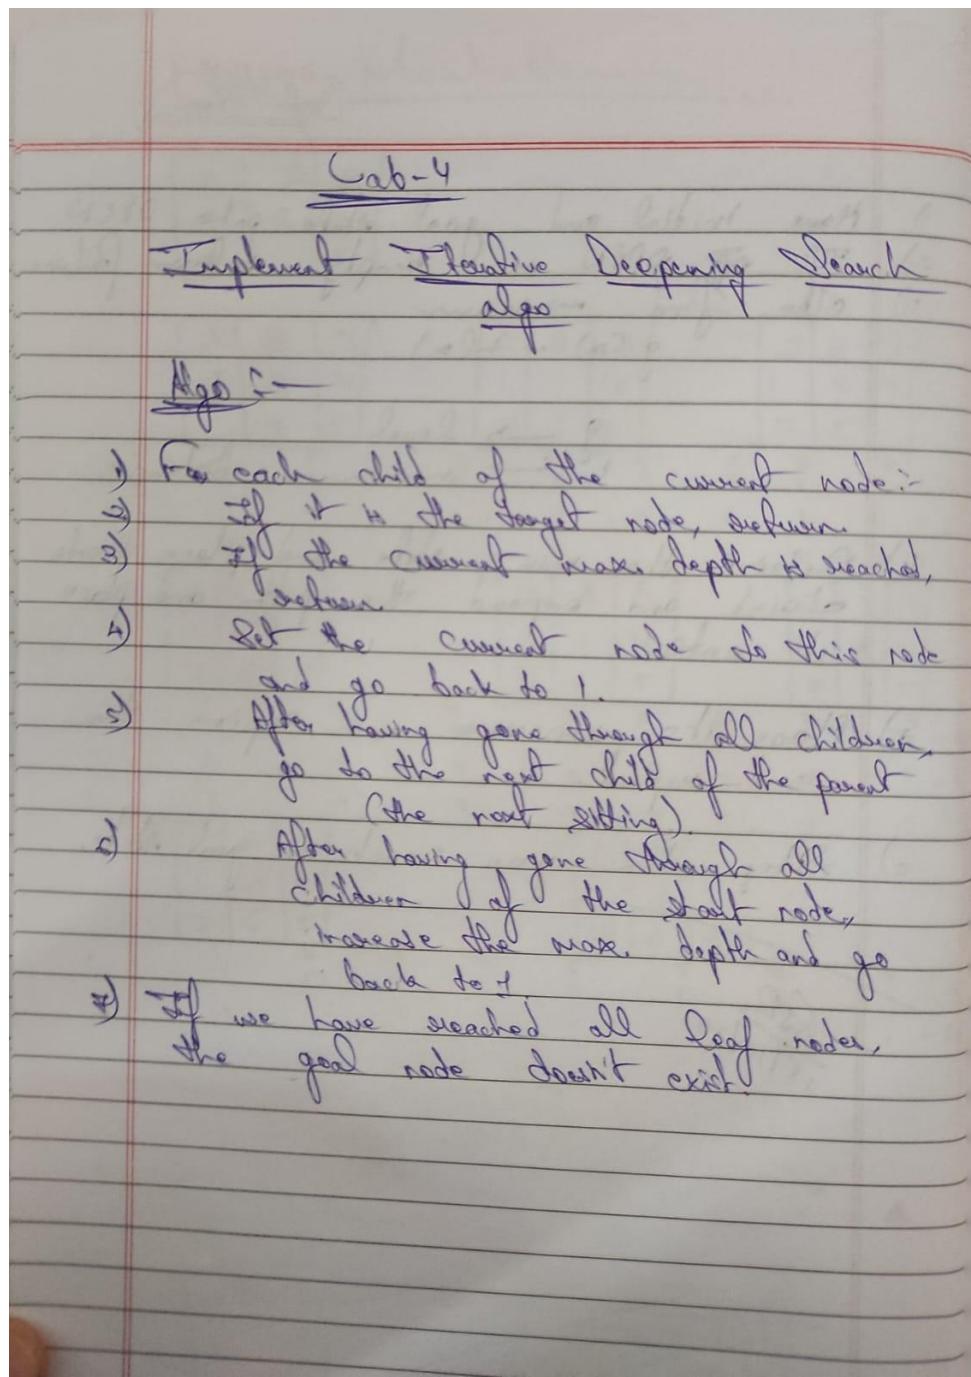

The screenshot shows a Google Colab notebook titled "Copy of Welcome To Colab". The code cell contains the provided Python script. The output cell displays the results of running the script. It shows two separate solutions for the 3x3 sliding puzzle. The first solution involves 10 moves, and the second involves 1 move. Each solution shows the state of the puzzle at each step, represented by a 3x3 grid of numbers.

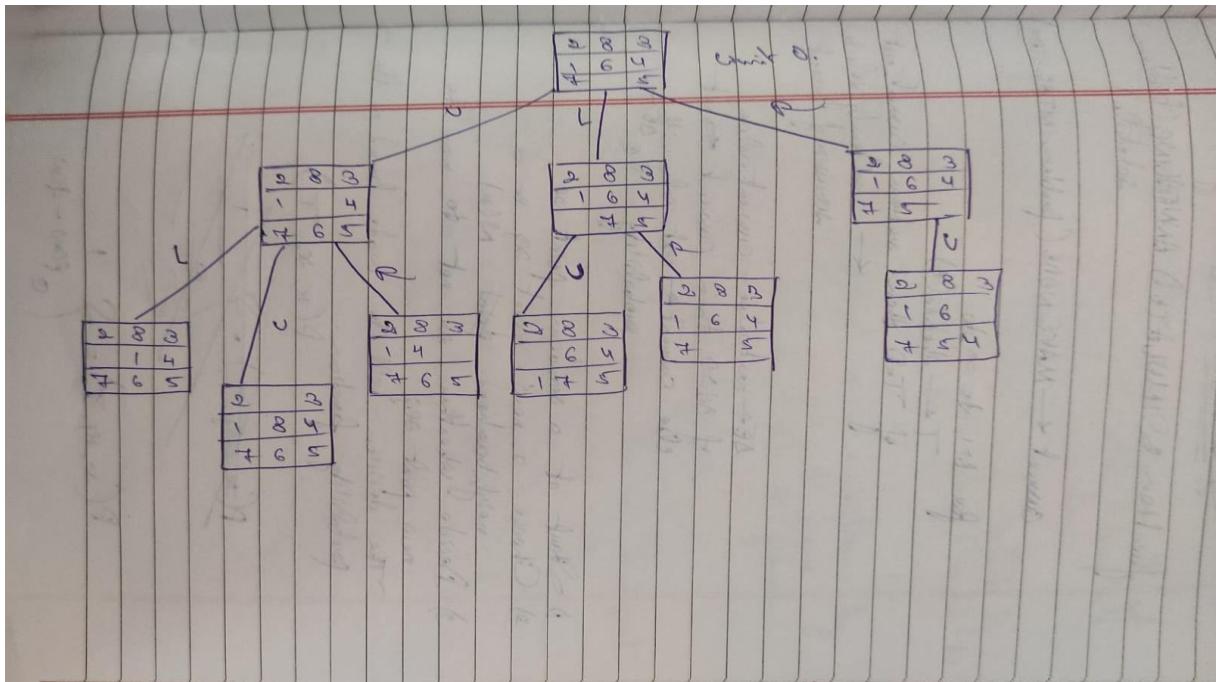

```

Number of moves: 10
Move 310:
Step 0:
1 | 2 | 3
-----
0 | 4 | 6
-----
7 | 5 | 8
-----
Step 1:
1 | 2 | 3
-----
7 | 4 | 6
-----
0 | 5 | 8
-----
Number of moves: 1
Move 311:
Step 0:
1 | 2 | 3
-----
0 | 4 | 6
-----
7 | 5 | 8
-----
Step 1:
0 | 2 | 3
-----
1 | 4 | 6
-----
7 | 5 | 8
-----
```

Implement Iterative deepening search algorithm

Algorithm:

Code:

```
from collections import deque
```

```
def bfs(start, goal):
    queue = deque([(start, [start], 0)]) # (node, path, level)
    visited = set([start])
    while queue:
        node, path, level = queue.popleft()
        if node == goal:
            return path, level
        for next_node in get_neighbors(node):
            if next_node not in visited:
                visited.add(next_node)
                queue.append((next_node, path + [next_node], level + 1))
    return None, None
```

```
def get_neighbors(node):
    neighbors = []
    for i in range(9):
        if node[i] == 0:
            x, y = i // 3, i % 3
            for dx, dy in [(-1, 0), (1, 0), (0, -1), (0, 1)]:
                nx, ny = x + dx, y + dy
                if 0 <= nx < 3 and 0 <= ny < 3:
                    n = list(node)
                    n[i], n[nx * 3 + ny] = n[nx * 3 + ny], n[i]
                    neighbors.append(tuple(n))
```

```

        break
    return neighbors

def print_board(board):
    board = [board[i:i+3] for i in range(0, 9, 3)]
    for row in board:
        print(" | ".join(str(x) for x in row))
        print("-----")

def main():
    start = tuple(int(x) for x in input("Enter the initial state (space-separated): ").split())
    goal = (1, 2, 3, 4, 5, 6, 7, 8, 0)
    path, level = bfs(start, goal)
    if path:
        print("Solution found:")
        for i, node in enumerate(path):
            print(f"Move {i}:")
            print_board(node)
            print()
        print(f"Number of moves: {level}")
    else:
        print("No solution found.")

if __name__ == "__main__":
    main()

```

Output:

The screenshot shows a Google Colab notebook titled "Copy of Welcome To Colab". The code cell contains the provided Python script for solving an 8-puzzle. The output cell shows the execution results:

```

Enter the initial state (space-separated): 1 2 3 0 4 6 7 5 8
Solution found:
Move 0:
1 | 2 | 3
-----
0 | 4 | 6
-----
7 | 5 | 8
-----
Move 1:
1 | 2 | 3
-----
4 | 0 | 6
-----
7 | 5 | 8
-----
Move 2:
1 | 2 | 3
-----
4 | 5 | 6
-----
7 | 0 | 8
-----
Move 3:
1 | 2 | 3
-----
4 | 5 | 6
-----
7 | 8 | 0
-----
Number of moves: 3

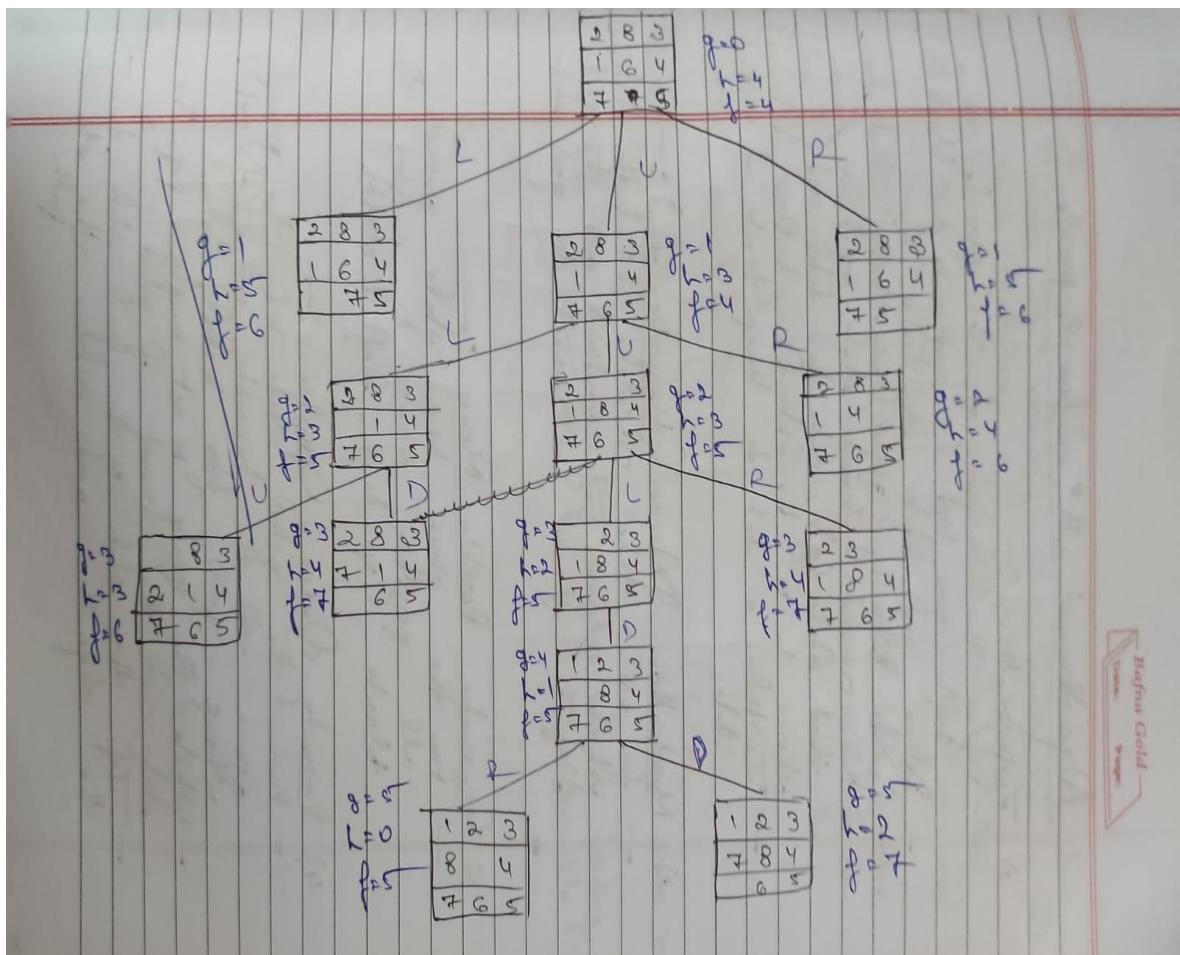

```

A browser notification dialog is displayed in the top right, asking if the user wants to enable browser notifications. The dialog has "OK" and "No thanks" buttons.

Program 3

Implement A* search algorithm

Algorithm:

Algorithm : A* for 8-puzzle

1) Initialization :-

- Define the initial state of the puzzle as a tuple or list. (0 represents the blank tile).
- Define goal state, similarly.
- Create priority queue (min-heap) that stores the current board state, cost to reach that state (g), estimated total cost ($f = g + h$) where h is heuristic (Manhattan distance).
- Initialize a set to keep track of visited states.

2) Manhattan Distance (Heuristic f_h) :-

- For each tile calculate Manhattan distance which is sum of vertical and horizontal distance from current to goal state.

3) Generate Possible Moves :-

- For the given board state generate all possible moves by moving the blank tile up, down, left, right.

4) Priority Queue Operations :-

- Push the initial state into the priority queue with the heuristic value of $g+h$, where $g=0$ for initial state.
- While the queue is not empty, pop the state with the lowest f value.
- If this state is the goal state, terminate the algorithm and return the state path.

- Otherwise, generate the successor of this state by moving the blank tile in all valid direction.
- For each successor state, calculate g (the cost to reach the successor) and f (total cost).
 - If the successor has not been visited or if a lower-cost path to the successor is found, push it into the priority queue.

5) Termination :-

- The algo. terminates when the goal state is reached
- If the queue becomes empty without finding solution, then the puzzle is unsolvable.

Using Manhattan

- 1) Have initial and goal state onto OPEN.
- 2) If ~~or~~ OPEN is empty return failure
- 3) else find minimum
 $g(s) + h(s)$

$g \rightarrow$ level
 $h \rightarrow$ minimum distance

- 4) Remove the min state and place it onto closed and expand the path and place it onto
- 5) Place its successor and explore them and repeat.
- 6) Stop when you reach the goal state.

Program 4

Implement Hill Climbing search algorithm to solve N-Queens problem

Algorithm:

Simulated Annealing

function SIMULATED ANNEALING(problem, schedule)

 current \leftarrow MAKE-NODE(problem, INIT-STAT)

 for $t=1$ to ∞ do

$T \leftarrow$ schedule(t)

 if $T=0$ then return current

 ← a randomly selected successor of current

ΔE ← next-value - current.value

 if $\Delta E > 0$ then current \leftarrow next

 else current \leftarrow next only with probability $e^{\Delta E/T}$

 1) Start at a random point x_0 .

 2) Choose a new point x_1 in a neighbourhood $N(x_0)$

 3) Decide whether or not to move to new point x_1 .

 The decision will be made based on the probability function.

$P(x_0, x_1, T) = \frac{1}{e^{(f(x_1) - f(x_0)) / T}}$

~~$P(x_0, x_1, T) = \frac{1}{1 + e^{(f(x_1) - f(x_0)) / T}}$~~

For 8 queen problem :-

- 1) Initialise: Start with arrangement of queens, set initial temp & cooling parameters.
- 2) Evaluate fitness: Calculate no. of conflicts by swapping 2 queens. Calculate its fitness.
- 3) Generate Neighbours: Create a neighbour by swapping 2 queens. Calculate its fitness.
- 4) Accept or reject neighbour.
- 5) Gradually reduce the temperature & repeat until the temp is very low.
- 6) Return the best arrangement found.
~~Output Best state found [4 7 5 0 6 3 7 2].
Number of conflicts = 2~~

Program 8

Create a knowledge base consisting of first order logic statements and prove the given query using forward reasoning.

Algorithm:

FOL Forward Logic

D Create a knowledge base consisting of first order statements and prove the given query using forward reasoning.

Algo :

function FOL-FC-Ack (KB, α) return a substitution or false

inputs: KB, the knowledge base, a set of first order definite clauses, α , the query, an atomic sentence.

local variables: new, the sentence inferred on each iteration

repeat until new is empty

 new $\leftarrow \emptyset$

 for each rule in KB do

$\{ p_1 \wedge \dots \wedge p_r \rightarrow q \} \leftarrow$ STANDARDIZE-VARIABLES (rule)

 for each θ such that

$\text{SUBST}(\theta, p_1 \wedge \dots \wedge p_r) = \text{SUBST}(\theta, p'_1 \wedge \dots \wedge p'_r)$

 for some p_i, p'_i in KB

$q' \leftarrow \text{SUBST}(\theta, q)$

 if q' does not unify with some sentence already in KB
 then new \leftarrow new $\cup \{ q' \}$

Date: _____
Page: _____

add q' to rules
 $\emptyset \leftarrow \text{UNIFY}(q', x)$
 if \emptyset is not fail
 then reduce \emptyset

add new to KB
 return false.

Representation in FOL ↴

It is a crime for an American to sell
 weapon to hostile nation

lets say p , q and x are variable

$\text{American}(p) \wedge \text{Weapon}(q) \wedge \text{Sells}(p, q, x) \wedge$
 $\text{Hostile}(x) \Rightarrow \text{Criminal}(p)$

Country A has some missiles.

$\exists x \text{Missile}(A, x) \wedge \text{Missile}(x)$

Existential instantiation introducing a new
 constant T_1 :

$\text{Missile}(A, T_1)$
 $\text{Missile}(T_1)$

All of the missiles were sold to country
 A by Robert

$\forall x \text{Missile}(x) \wedge \text{Own}(A, x) \Rightarrow \text{Sells}(\text{Robert}, x, A)$

~~Missiles are weapons~~
 $\text{Missile}(x) \Rightarrow \text{Weapon}(x)$

Enemy of America is known as hostile

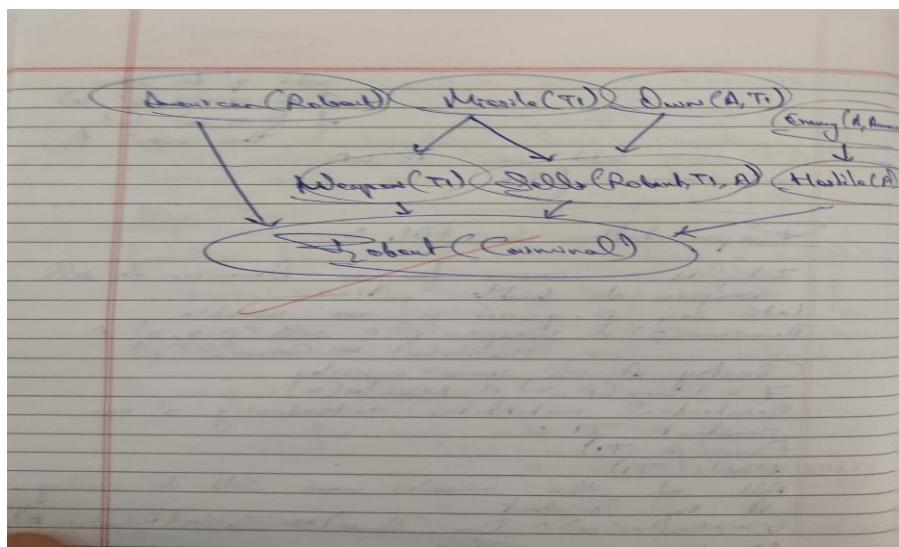

$\forall x \text{Enemy}(x, \text{America}) \Rightarrow \text{Hostile}(x)$

Robert is an American

$\text{American}(\text{Robert})$

The Country A, an enemy of America

$\text{Enemy}(A, \text{America})$

Program 9

Create a knowledge base consisting of first order logic statements and prove the given query using Resolution

Algorithm:

Bafna Gold
Date: _____
Page: _____

Lab - 9

Convert a given first order logic statement into Conjunctive Normal form (CNF)

Basic steps for proving a conclusion S given premise P_1, P_2, \dots, P_n

Call expression in FOL

- 1) Convert all sentences to CNF
- 2) Negate conclusion S and convert result to CNF
- 3) Add Negated conclusion $\neg S$ to the premise clauses
- 4) Repeat until contradiction or no progress to node.
 - a) Select 2 clauses (call them parent clauses)
 - b) Resolve them together, performing all required unifications
 - c) If resultant is the empty clause, a contradiction has been found (i.e. S follows from the premise).
 - d) If not, add resultant to the premises.

e.g.: Given the KB as Premises:

- 1) John likes all kind of food.
- 2) Apple and vegetables are food.
- 3) Anything anyone eats and not killed is food.
- 4) Amit eats peanuts and still alive.
- 5) Harry eats everything that amil eats.
- 6) Anyone who is alive implies not killed.
- 7) Anyone who is not killed implies alive.

Response variables are standardize variables

- 1) $\text{Hx} \rightarrow \text{food}(x) \vee \text{likes}(\text{John}, x)$
- 2) $\text{food}(\text{apple}) \wedge \text{food}(\text{vegetable})$
- 3) $\forall y, z \exists \text{eat}(y, z) \vee \text{killed}(y) \vee \text{food}(z)$
- 4) $\text{eat}(\text{Anil}, \text{peanuts}) \wedge \text{alive}(\text{Anil})$
- 5) $\forall w \exists \text{eat}(\text{Anil}, w) \vee \text{eat}(\text{Harry}, w)$
- 6) $\forall g \exists \text{alive}(g) \vee \exists \text{killed}(g)$
- 7) $\forall k \exists \text{killed}(k) \vee \text{alive}(k)$
- 8) $\exists l \text{likes}(\text{John}, \text{peanuts})$

Deep universal quantifiers

- 1) $\exists \text{food}(x) \vee \text{likes}(\text{John}, x)$
- 2) $\text{food}(\text{apple}) \wedge \text{food}(\text{vegetable})$
- 3) $\exists \text{eat}(y, z) \vee \text{killed}(y) \vee \text{food}(z)$
- 4) $\exists \text{eat}(\text{Anil}, \text{peanuts}) \wedge \text{alive}(\text{Anil})$
- 5) $\exists \text{eat}(\text{Anil}, w) \vee \text{eat}(\text{Harry}, w)$
- 6) $\exists \text{alive}(g) \vee \exists \text{killed}(g)$
- 7) $\exists \text{killed}(k) \vee \text{alive}(k)$
- 8) $\exists l \text{likes}(\text{John}, \text{peanuts})$

$\exists l \text{likes}(\text{John}, \text{peanuts}) \quad \exists \text{food}(x) \vee \text{likes}(\text{John}, x)$

$\exists \text{peanut}/\exists y$

$\exists \text{food(peanut)} \quad \exists \text{eat}(y, z) \vee \text{killed}(y) \vee \text{food}(z)$

$\exists \text{peanut}/\exists y$

$\exists \text{eat}(y, \text{peanut}) \vee \text{killed}(y) \quad \exists \text{eat}(\text{Anil}, \text{peanuts})$

$\exists \text{Anil}/\exists y$

$\exists \text{killed}(\text{Anil}) \quad \exists \text{alive}(g) \vee \exists \text{killed}(g)$

$\exists \text{Anil}/\exists g$

Franchise proposed

bove by substitution that:

John likes peanuts.

- 1) $\text{Hx}: \text{food}(x) \rightarrow \text{likes}(\text{John}, x)$
- 2) $\text{food}(\text{apple}) \wedge \text{food}(\text{vegetable})$
- 3) $\forall z, y: \text{eat}(x, y) \wedge \exists \text{killed}(x) \rightarrow \text{food}(y)$
- 4) $\text{eat}(\text{Anil}, \text{peanuts}) \wedge \text{alive}(\text{Anil})$
- 5) $\text{Hx}: \text{eat}(\text{Anil}, x) \rightarrow \text{eat}(\text{Harry}, x)$
- 6) $\text{Hx}: \text{alive}(x) \rightarrow \exists \text{killed}(x)$
- 7) $\text{Hx}: \exists \text{killed}(x) \rightarrow \text{alive}(x)$
- 8) $\exists l \text{likes}(\text{John}, \text{Peanuts})$

Clarification implications

- 1) $\forall x \exists \text{food}(x) \vee \text{likes}(\text{John}, x)$
- 2) $\text{food}(\text{apple}) \wedge \text{food}(\text{vegetable})$
- 3) $\forall y, z \exists (\text{eat}(y, z) \wedge \exists \text{killed}(y)) \vee \text{food}(z)$
- 4) $\text{eat}(\text{Anil}, \text{peanuts}) \wedge \text{alive}(\text{Anil})$
- 5) $\text{Hx} \exists \text{eat}(\text{Anil}, x) \vee \text{eat}(\text{Harry}, x)$
- 6) $\text{Hx} \exists \text{alive}(x) \vee \exists \text{killed}(x)$
- 7) $\text{Hx} \exists (\exists \text{killed}(x) \vee \text{alive}(x))$
- 8) $\exists l \text{likes}(\text{John}, \text{Peanuts})$

More negation (\neg) involved

- 1) $\text{Hx} \neg \text{food}(x) \vee \text{likes}(\text{John}, x)$
- 2) $\neg \text{food}(\text{apple}) \wedge \neg \text{food}(\text{vegetable})$
- 3) $\forall y, z \neg \text{eat}(x, y) \vee \neg \text{killed}(x) \wedge \neg \text{food}(z)$
- 4) $\neg \text{eat}(\text{Anil}, \text{peanuts}) \wedge \neg \text{alive}(\text{Anil})$
- 5) $\text{Hx} \neg \text{eat}(\text{Anil}, x) \vee \neg \text{eat}(\text{Harry}, x)$
- 6) $\text{Hx} \neg \text{alive}(x) \vee \neg \text{killed}(x)$
- 7) $\text{Hx} \neg \exists \text{killed}(x) \vee \neg \text{alive}(x)$
- 8) $\neg \text{likes}(\text{John}, \text{peanuts})$

Output: Derived facts: → food(peanut)
 → eats(y, peanut)
 ∨ killed(y)
 killed(Anil)
 ∨ alive(Anil)
 ↗
 Person likes (John, peanut).

Code:

```

# Knowledge Base (KB)
facts = {
  "Eats(Anil, Peanuts)": True,
  "not Killed(Anil)": True,

```

Output:

Derived Fact: Food(Peanuts)
 Derived Fact: Likes(John, Peanuts)
 Proven: Likes(John, Peanuts)

Program 10

Implement Alpha-Beta Pruning.

Algorithm:

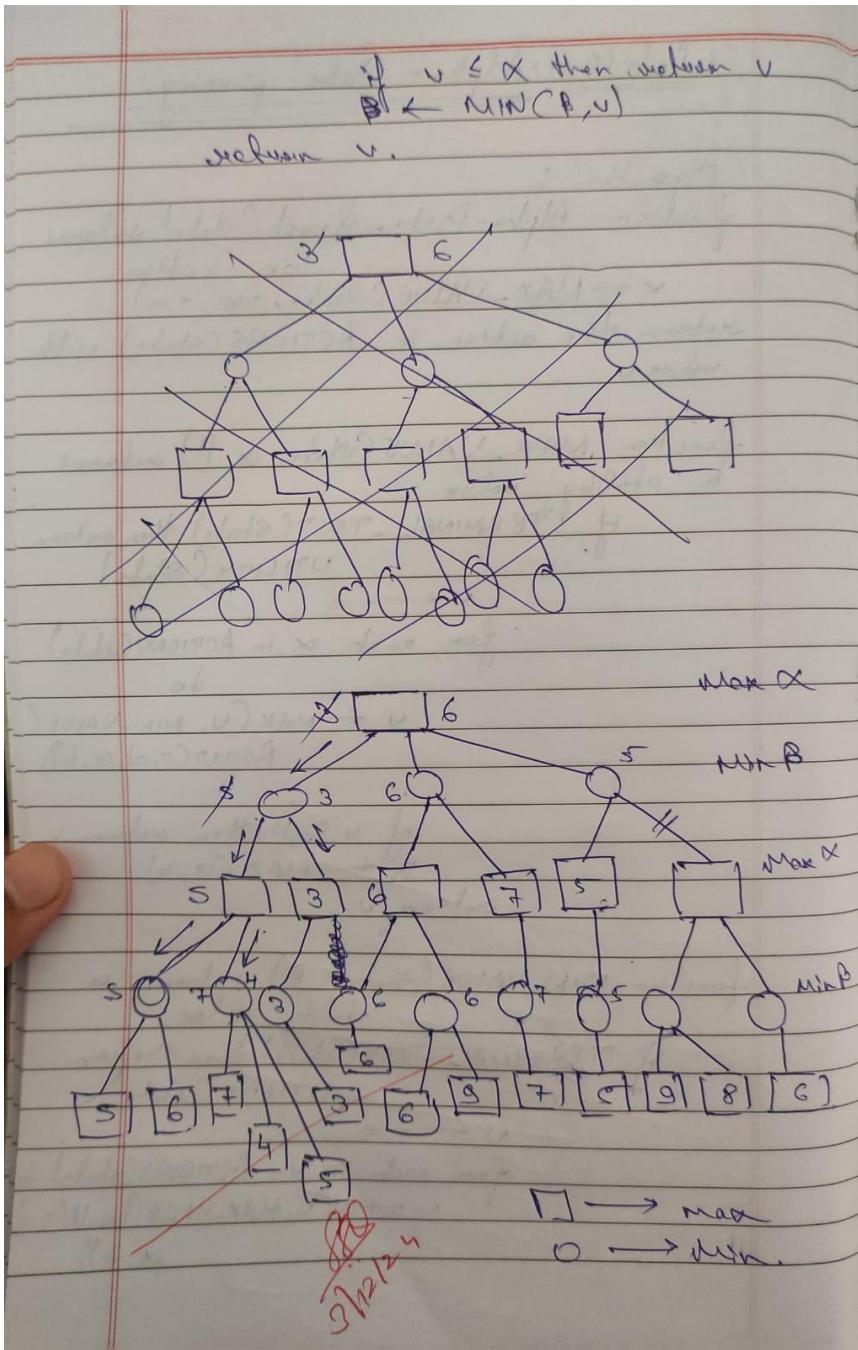

Lab 10 : Alpha - Beta pruning

Algorithm :

function Alpha-Beta-Search (state) returns
on a action.
 $v \leftarrow \text{MAX-VALUE} (\text{state}, -\infty, +\infty)$
return the action in $\text{ACTIONS}(\text{state})$ with
value v .

function MAX-VALUE (state, α, β) returning
a utility value.
if TERMINAL-TEST (state) then return
UTILITY (state)
 $v \leftarrow -\infty$
for each a in $\text{ACTIONS}(\text{state})$
do
 $v \leftarrow \text{MAX} (v, \text{MIN-VALUE} ($
 $\text{RESULT}(s, a), \alpha, \beta))$
if $v \geq \beta$ then return v
 $\alpha \leftarrow \text{MAX} (\alpha, v)$
return v

function MIN-VALUE (state, α, β) returning a
utility value
if TERMINAL-TEST (state) then return
UTILITY (state)
 $v \leftarrow +\infty$
for each a in $\text{ACTIONS}(\text{state})$ do
 $v \leftarrow \text{MIN} (v, \text{MAX-VALUE} (\text{RESULT}(s, a),$
 $\alpha, \beta))$

Code:

```
import math
```

```
def minimax(depth, index, maximizing_player, values, alpha, beta):
  # Base case: when we've reached the leaf nodes
  if depth == 0:
    return values[index]
